What Is the Analytic Hierarchy Process (AHP)?

Definition and Overview

The Analytic Hierarchy Process is a multi-criteria decision-making (MCDM) technique that helps prioritize options by quantifying subjective judgments. It transforms qualitative assessments into quantitative weights, enabling decision-makers to compare different criteria and alternatives systematically.

Key Features of AHP

- Hierarchical Structure: Breaks down complex decisions into a hierarchy of goals, criteria, sub-criteria, and alternatives.
- Pairwise Comparisons: Uses pairwise comparisons to evaluate the relative importance of elements.
- Consistency Check: Incorporates a consistency ratio to ensure judgments are logical.
- Quantitative Results: Produces priority weights that reflect the most favored options.

The Role of Saaty in Developing AHP

Thomas L. Saaty introduced the AHP methodology, emphasizing the importance of structured decision-making processes. His contributions include:

- Creating a systematic approach for pairwise comparison matrices.
- Developing the consistency ratio to validate judgments.
- Publishing extensive research and guidelines to apply AHP across diverse fields.

Saaty's work revolutionized decision analysis by providing a practical, adaptable framework that combines subjective judgments with mathematical rigor.

The AHP Methodology: Step-by-Step Breakdown

Implementing AHP involves several stages, each crucial to deriving reliable results.

- Define the Problem and Set Goals

Start by clearly articulating the main decision or problem. Establish the primary goal that guides the entire process.

- Structure the Hierarchy

Organize the decision elements into a hierarchy:

- Level 1: Overall goal.
- Level 2: Criteria influencing the decision.
- Level 3: Sub-criteria (if any).
- Level 4: Alternatives/options under consideration.

- Conduct Pairwise Comparisons

Compare elements at each hierarchy level two at a time using a scale (commonly 1-9) to express relative importance or preference.

Example of Pairwise Comparison Scale:

| Scale Value | Description |

|-----|-----|

| 1 | Equal importance |

| 3 | Slightly more important |

| 5 | Significantly more important |

| 7 | Demonstrably more important |

| 9 | Absolutely more important |

| 2, 4, 6, 8 | Intermediate values for nuances |

- Calculate Priority Weights

Using the comparison matrices, compute the priority vectors (weights) for each element, often through eigenvector methods or normalization techniques.

- Check for Consistency

Calculate the Consistency Ratio (CR) to verify the judgments' logical coherence. A CR of less than 0.10 is generally acceptable.

- Aggregate the Results

Combine the weights across different hierarchy levels to determine the overall priority of each alternative.

- Make the Decision

Select the alternative with the highest overall priority score, reflecting the most favorable choice based on the analysis.
