What Are Hormones? An Introduction

Hormones are specialized chemical substances produced by endocrine glands and released into the bloodstream. They travel through the circulatory system to reach target cells or organs where they exert specific biological effects. As chemical messengers, hormones coordinate complex processes that sustain life, adapt to changes, and promote growth and development.

What Are Hormones Chemical Messengers?

Definition and Basic Concept

Hormones chemical messengers are signaling molecules produced by glands and specialized cells in the endocrine system. They are secreted directly into the bloodstream, allowing them to travel to distant target organs or tissues to exert their effects. Unlike neurotransmitters, which operate primarily within the nervous system, hormones function as long-distance communicators coordinating systemic physiological processes.

Key Features of Hormones Chemical Messengers

- Potency: Small amounts can trigger significant biological responses.
- Regulation: Their secretion is tightly controlled by feedback mechanisms to maintain balance.

Types of Hormones Chemical Messengers

Hormones are broadly classified based on their chemical structure. Understanding these categories is crucial because it influences their mechanism of action, transport, and receptor interaction.

- Peptide and Protein Hormones

gene expression directly.

- Amine Hormones

- Structure: Derived from amino acids like tyrosine and tryptophan.
- Examples: Thyroid hormones (T3 and T4), adrenaline, noradrenaline.
