

CALCULATION DEAERATOR BALANCE Tutorial

Calculation of Deaerator Balance: An In-Depth Guide

Calculation deaerator balance is a fundamental process in the design, operation, and troubleshooting of deaerators within steam systems. Deaerators are crucial equipment used to remove dissolved gases, primarily oxygen and carbon dioxide, from feedwater to prevent corrosion in downstream boiler and piping systems. Proper calculation of the deaerator balance ensures optimal removal of these gases, efficient operation, and minimal energy consumption. This article provides a comprehensive overview of the principles, methods, and steps involved in calculating the deaerator balance, including the mass and energy balances, typical calculations, and practical considerations.

Understanding the Role of a Deaerator

Function and Importance

Deaerators are designed to eliminate dissolved gases from boiler feedwater, which can cause severe corrosion and reduce system efficiency. They operate by heating the feedwater and exposing it to a controlled environment where gases are released and vented away. Proper operation hinges on maintaining a precise balance of mass and energy within the deaerator to ensure effective gas removal while conserving energy.

Types of Deaerators

- Tray Deaerators: Use trays to contact feedwater with steam, promoting gas release.
- Spray Deaerators: Use spray nozzles to atomize feedwater, enhancing heat transfer and gas removal.
- Combination Units: Combine features of both for optimized performance.

Fundamental Principles of Deaerator Balance Calculation

Mass Balance

The mass balance involves accounting for all incoming and outgoing streams of water and gases. It ensures that the amount of feedwater, vented gases, and makeup water are accurately considered.

Basic mass balance equation:

$$\text{Inflow} = \text{Outflow} + \text{Accumulation}$$

For steady-state operation, accumulation is zero, simplifying the calculations.

Energy Balance

The energy balance accounts for the heat transfer processes within the deaerator, including heating of feedwater, vaporization, and venting. It ensures that the temperature and pressure conditions are maintained for optimal gas removal.

Basic energy balance equation:

$$\text{Energy In} = \text{Energy Out} + \text{Energy Losses}$$

This involves calculating the enthalpy of incoming water and steam, as well as the heat carried away by vented gases.

Step-by-Step Calculation of Deaerator Balance

1. Data Collection and Input Parameters

Gather all necessary data:

- Feedwater flow rate (Q_{fw})
- Feedwater temperature (T_{fw})
- Feedwater pressure (P_{fw})
- Steam inlet parameters (pressure, temperature, flow rate)
- Vent gas flow rate and composition
- Make-up water flow (Q_m)
- Operating pressure and temperature of deaerator (P_d, T_d)

2. Calculating Dissolved Gas Content

Use Henry's law or saturation tables to determine the initial dissolved oxygen (DO) and carbon dioxide (CO₂) levels in the feedwater. Standard concentrations are often expressed in ppm.

Example:

$$\text{DO}_{\text{initial}} = \text{value from feedwater analysis}$$

3. Estimating Gas Removal Efficiency

Determine the desired removal efficiency, typically expressed as a percentage:

- For oxygen: 98-99%
- For carbon dioxide: 95-98%

The removal efficiency depends on the temperature, pressure, and contact time within the deaerator.

4. Calculating Gas Removal Rates

Using the initial gas concentrations and the removal efficiency:

$$\text{Gas removed} = \text{Initial dissolved gas} \times \text{Efficiency}$$

The vent gas flow rate (Q_{vent}) can then be estimated:

$$Q_{\text{vent}} = \frac{\text{Gas removed} \times \text{molecular weight}}{\text{gas density}}$$

5. Heat Balance Calculations

Calculate the heat required to raise feedwater to the deaerator temperature:

$$Q_{\text{heat}} = Q_{\text{fw}} \times (h_{\text{T}} - h_{\text{T}_{\text{in}}})$$

Where:

- h_{T} : Enthalpy at deaerator temperature
- $h_{\text{T}_{\text{in}}}$: Enthalpy of incoming feedwater

Determine the heat supplied by steam:

$$Q_{\text{steam}} = m_{\text{steam}} \times (h_{\text{steam}} - h_{\text{condensate}})$$

Match the heat input with the heat needed to raise feedwater temperature and vaporize part of the water, considering losses.

6. Calculating Vent and Blowdown Flows

- Vented gases: Remove gases along with non-condensable gases.
- Blowdown: Periodic removal of concentrated impurities; its flow rate impacts the overall mass balance.

Calculate blowdown rate based on boiler operation and water quality standards.

7. Final Balancing and Verification

Ensure that the sum of all inflows equals outflows:

- Total feedwater + makeup water = total vented gases + blowdown + condensate return

Verify that the calculated dissolved gas removal aligns with system requirements and operational constraints.

Practical Considerations in Deaerator Balance Calculation

Operating Conditions

- Pressure and temperature significantly influence gas solubility.
- Higher temperatures reduce gas solubility, improving removal efficiency.

Gas Laws and Solubility Data

Use Henry's law and published solubility tables for accurate estimation:

- Gas solubility decreases with increasing temperature.
- Partial pressures of gases influence removal rates.

Efficiency and Performance Optimization

- Proper tray or spray design enhances contact.
- Adequate venting ensures removal of gases.
- Regular monitoring of dissolved oxygen levels maintains system integrity.

Common Challenges and Troubleshooting

- Insufficient venting leads to oxygen carryover.
- Overheating can cause corrosion.
- Improper balance causes inefficiency and increased energy consumption.

Conclusion

Accurate calculation of the deaerator balance is essential for efficient and reliable operation of steam systems. It involves comprehensive mass and energy balances, understanding of thermodynamic principles, and practical considerations related to system design and operation. By systematically following the steps?gathering data, estimating gas removal, performing heat calculations, and verifying inflow-outflow balance?engineers can optimize deaerator performance, minimize energy costs, and extend equipment lifespan. Properly calculated and maintained deaerator balances are vital for preventing corrosion, ensuring water quality, and achieving overall plant efficiency.

Calculation of deaerator balance is a critical aspect of boiler feedwater system management, ensuring that the deaerator operates efficiently, reliably, and safely. Proper deaerator balance involves understanding and optimizing the inputs and outputs of the deaerator to maintain desired water quality, prevent corrosion, and maximize system performance. Whether you're an engineer, operator, or maintenance professional, grasping the fundamentals of deaerator balance calculations is essential for effective plant operation and troubleshooting.

Introduction to Deaerator Balance

A deaerator is a device used to remove dissolved gases?primarily oxygen and carbon dioxide?from boiler feedwater. These gases can cause corrosion inside the boiler and associated piping, leading to reduced equipment lifespan and increased maintenance costs. The deaerator achieves this by heating the feedwater and stripping gases through a combination of temperature control, steam sparging, and venting.

Achieving a proper deaerator balance means ensuring that the amount of gases removed aligns with the incoming water quality, steam input, venting capacity, and other operational parameters. An imbalance can lead to inefficient deaeration, higher oxygen levels in the feedwater, or unnecessary steam and vent losses.

Fundamental Principles of Deaerator Balance

Before diving into calculations, it's important to understand the key components involved:

- Inflow (Feedwater): The water entering the deaerator, which contains dissolved gases.
- Steam Input: The steam used to heat the water and strip gases.
- Venting (Vent): The removal of gases and non-condensable impurities.
- Outflow (Deaerated Water): The treated water sent to the boiler.

The balance involves matching these inputs and outputs to ensure efficient operation, minimal losses, and water quality standards.

Key Parameters in Deaerator Balance

To perform a comprehensive calculation, you need to know or measure:

- Feedwater flow rate (Q_{fw}): Typically in kg/hr or m³/hr.
- Inlet water temperature (T_{in}): Usually in °C.
- Inlet dissolved oxygen (DO_{in}): in ppm or mg/L.
- Outlet water temperature (T_{out}): Usually close to saturation temperature at operating pressure.
- Steam consumption (Q_{steam}): in kg/hr.
- Vapor vent rate (Q_{vent}): in kg/hr of gases vented.
- Gases in water: Mainly oxygen and carbon dioxide, which need to be reduced to acceptable levels.

Step-by-Step Guide to Calculating Deaerator Balance

- Determine the Inlet Dissolved Gases

The initial step is to assess the amount of dissolved oxygen (DO) and CO₂ in the incoming water:

- Dissolved Oxygen (DO):

DO_{in} (mg/L) can be measured directly or estimated via water quality analysis.

- Dissolved Carbon Dioxide (CO₂):

Similarly measured or estimated.

- Calculate the Gas Load in the Incoming Water

Convert dissolved gases into total gas load:

- Oxygen load (mg/L):

$$O_2_load = DO_in \times Q_fw$$

- CO₂ load (mg/L):

$$CO_2_load = CO_2_in \times Q_fw$$

Total gas load is then:

$$Total\ gas\ (mg) = O_2_load + CO_2_load$$

- Estimate the Gas Removal Efficiency

Deaerators typically aim to reduce DO to less than 10 ppb (parts per billion) and CO₂ to minimal levels. The efficiency depends on:

- Temperature of the water
- Contact time
- Venting capacity
- Steam purity

Assuming a target reduction, the amount of gases removed must match the incoming load minus the residual gases.

- Calculate the Steam Requirement for Gas Stripping

The stripping of gases requires heating and steam:

- Heat transfer:

To heat the water from inlet to saturation temperature.

- Steam consumption:

The amount of steam needed depends on:

- The heat needed to raise water temperature:

$$Q_{\text{heat}} = Q_{\text{fw}} C_p (T_{\text{sat}} - T_{\text{in}})$$

where C_p is specific heat of water (~4.18 kJ/kg·K).

- The latent heat to vaporize gases:

Gases are removed via venting, so the vent rate must carry the gases away.

- Steam for stripping:

The amount of steam required to effectively strip gases is generally estimated based on empirical data or plant-specific design parameters, often expressed as:

$$Q_{\text{steam}} = \text{Gas removal rate steam-to-gas ratio}$$

Typical steam-to-gas ratios are in the range of 0.2 to 0.5 kg steam per kg of gases removed.

- Determine Venting Rate

The vent rate (Q_{vent}) is directly related to the gas removal:

$$Q_{\text{vent}} = \text{Gas removal rate (kg/hour)}$$

Where:

- Gas removal rate depends on the initial dissolved gas content and the efficiency of the deaerator.

- Establish the Balance Equation

Putting it all together, the deaerator balance can be summarized as:

- Input side:
 - Water inflow: Q_{fw}
 - Gas load: from dissolved gases
- Output side:
 - Deaerated water: Q_{fw} (minus minor losses)
 - Vent gases: Q_{vent}
 - Steam input: Q_{steam}

Balance equation:

$$Q_{vent} = \text{Gas load in feedwater} - \text{residual gases in outflow}$$

and

$$Q_{steam} = \text{heat required to raise water temperature} + \text{energy to strip gases}$$

Practical Example

Suppose:

- Feedwater flow rate: 10,000 kg/hr
- Inlet DO: 8 mg/L
- Inlet temperature: 25°C
- Saturation temperature at operating pressure: 120°C
- Target residual DO:

Step 1: Calculate initial oxygen load:

$$O_2 \text{ load} = 8 \text{ mg/L} (Q_{fw} \text{ in L/hr})$$

Since 1 kg of water = 1 L, then:

$$Q_{fw} \text{ in L/hr} = 10,000 \text{ kg/hr}$$

$$O_2 \text{ load} = 8 \text{ mg/L} \times 10,000 \text{ L/hr} = 80,000 \text{ mg/hr} = 80 \text{ g/hr}$$

Step 2: Convert to molar quantities and determine gases to be vented.

- Molar mass of O_2 = 32 g/mol

- Moles of oxygen per hour:

$$80 \text{ g/hr} \div 32 \text{ g/mol} = 2.5 \text{ mol/hr}$$

- Since gases are vented, the vent rate of oxygen is approximately 2.5 mol/hr, or about 80 g/hr.

Step 3: Determine steam requirement for stripping:

- Using an empirical steam-to-gas ratio of 0.3:

$$Q_{steam} = 0.3 \times 80 \text{ g/hr} = 24 \text{ g/hr}$$

- Convert to kg/hr:

$$24 \text{ g/hr} \div 1000 = 0.024 \text{ kg/hr}$$

This indicates a minimal steam requirement for venting gases, but in practice, the actual steam used is higher due to heat transfer needs.

Step 4: Finalize the balance:

- Steam supplied: based on heat needed to raise water to saturation temperature plus gas stripping energy.

- Vent gases: approximately matching the initial oxygen load, with adjustments based on efficiency.

Tips for Accurate Deaerator Balance Calculation

- Regular Sampling: Measure inlet and outlet water quality regularly to determine actual gas loads.
- Empirical Data: Use plant-specific data and experience to refine steam-to-gas ratios.
- Monitoring Instruments: Employ dissolved oxygen meters and vent gas analyzers for real-time data.
- Simulation Software: Utilize process simulation tools for complex calculations and scenario analysis.
- Maintenance: Keep vents, heat exchangers, and controls in optimal condition to ensure accurate balances.

Conclusion

Calculation of deaerator balance is a vital process that ensures the effective removal of dissolved gases from boiler feedwater while optimizing steam and vent usage. It involves understanding the relationship between incoming water quality, heat transfer, gas stripping efficiencies, and venting capacity. By systematically analyzing each component and applying fundamental principles, plant engineers and operators can maintain a well-balanced deaerator, leading to improved system reliability, reduced corrosion, and energy savings.
